

Introduction to Operating System

Dr. Debasmita Pradhan
School of Computer Application
KIIT Deemed to be University
Bhubaneswar

Text Book:

Operating System Concepts

A. Silberschatz, P. Galvin, G. Gagne

EVALUATION SCHEME

- ▶ End Term (50)
- ▶ Mid Term(20, Evaluated from 40)
- ▶ Teachers Assessment(30)
 - ▶ Surprise Test
 - ▶ Quiz
 - ▶ Assignment

Objectives

- ▶ What operating System does
- ▶ To describe the basic organization of computer systems
- ▶ To give an overview of the many types of computing environments
- ▶ To provide a grand tour of the major components of operating systems
- ▶ To explore several open-source operating systems

Operating Systems

What is an Operating System?

- ▶ A program that acts as an intermediary between a user of a computer and the computer hardware
- ▶ Operating system goals:
 - ▶ Execute user programs and make solving user problems easier
 - ▶ Make the computer system convenient to use
 - ▶ Use the computer hardware in an efficient manner

What Operating Systems Do

- ▶ Depends on the point of view
 - ▶ User View
 - ▶ For a single user PC Users want convenience, **ease of use** and **good performance**
 - ▶ Don't care about **resource utilization**
 - ▶ But shared computer such as **mainframe** or **minicomputer** must keep all users happy(Resource Sharing)
 - ▶ Users of dedicate systems such as **workstations** have dedicated resources but frequently use shared resources from **servers**
 - ▶ **System View**
 - ▶ An OS is viewed as resource allocator
- ▶ Handheld computers are optimized for usability and battery life
- ▶ Some computers have little or no user interface, such as embedded computers in devices and automobiles

Operating System Definition

- ▶ OS is a **resource allocator**
 - ▶ Manages all resources
 - ▶ Decides between conflicting requests for efficient and fair resource use
- ▶ OS is a **control program**
 - ▶ Controls execution of programs to prevent errors and improper use of the computer

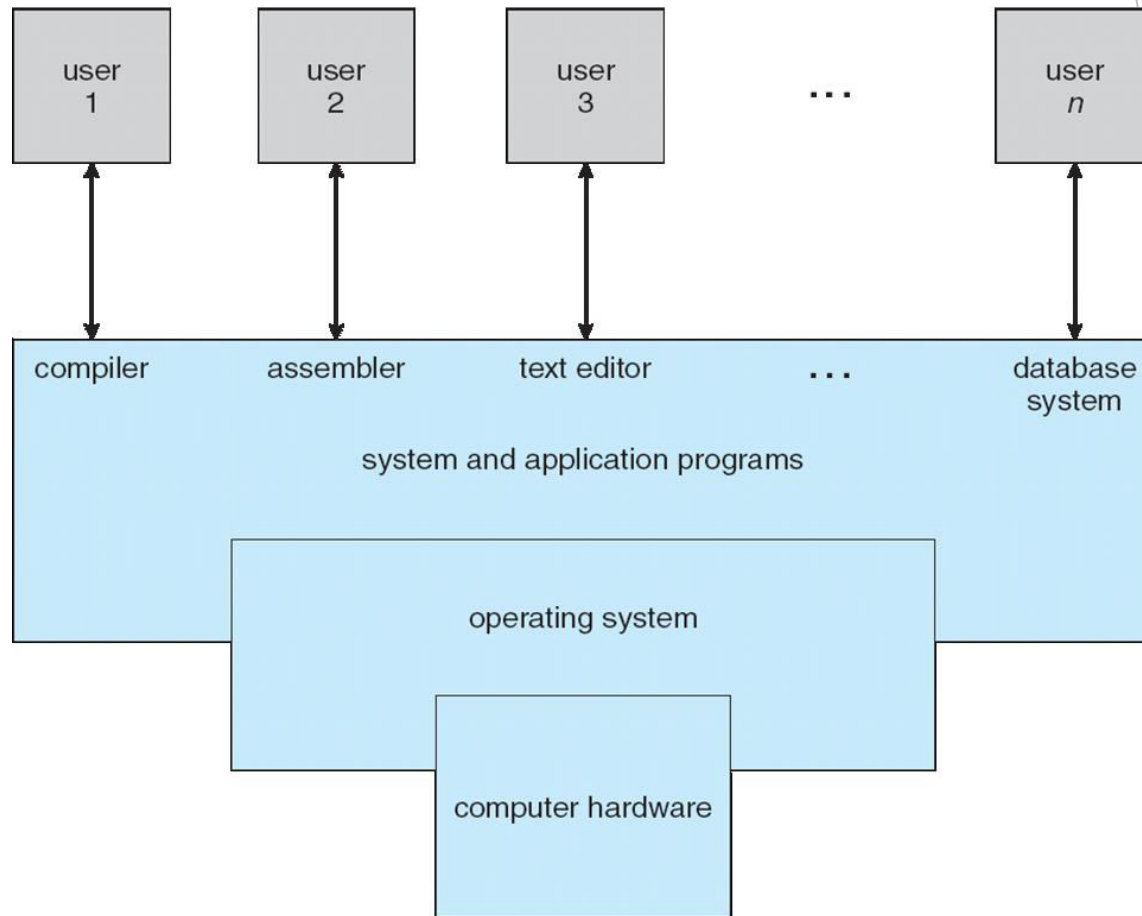

Operating System Definition (Cont.)

- ▶ No universally accepted definition
- ▶ “Everything a vendor ships when you order an operating system” is a good approximation
 - ▶ But varies wildly
- ▶ “The one program running at all times on the computer” is the **kernel**.
- ▶ Everything else is either
 - ▶ a system program (ships with the operating system) , or
 - ▶ an application program.

Computer System Structure

- ▶ Computer system can be divided into four components:
 - ▶ Hardware - provides basic computing resources
 - ▶ CPU, memory, I/O devices
 - ▶ Operating system
 - ▶ Controls and coordinates use of hardware among various applications and users
 - ▶ Application programs - define the ways in which the system resources are used to solve the computing problems of the users
 - ▶ Word processors, compilers, web browsers, database systems, video games
 - ▶ Users
 - ▶ People, machines, other computers

Four Components of a Computer System

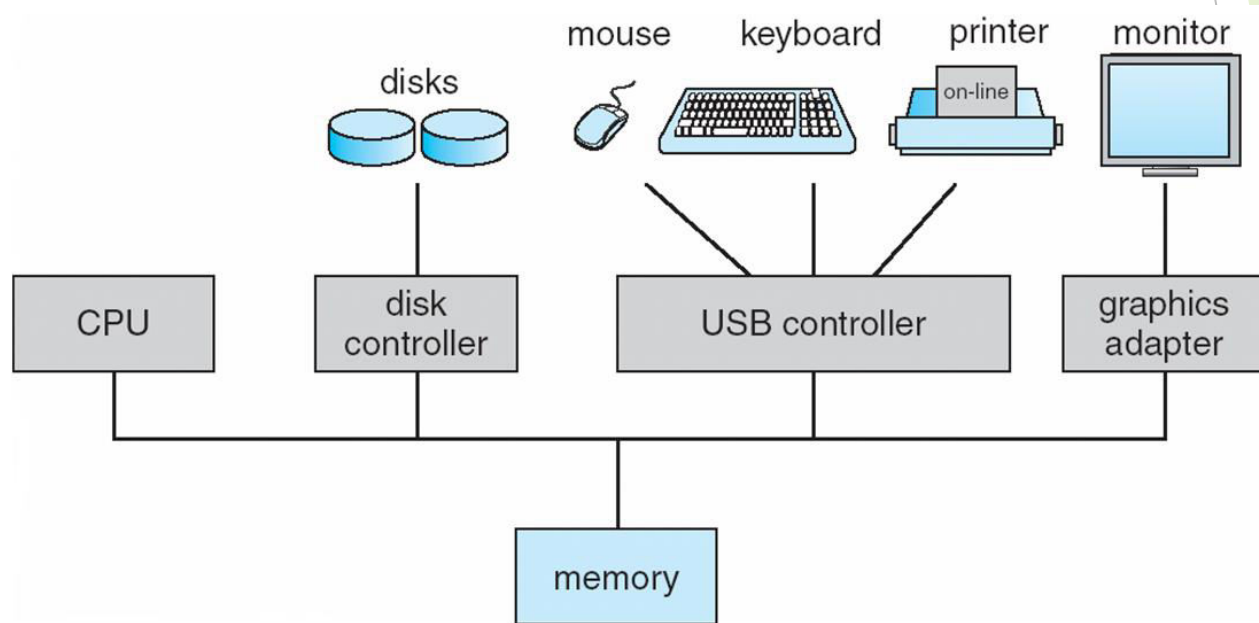

Computer Startup

- ▶ **bootstrap program** is loaded at power-up or reboot
 - ▶ Typically stored in ROM or EPROM, generally known as **firmware**
 - ▶ Initializes all aspects of system
 - ▶ Loads operating system kernel and starts execution
 - ▶ Once kernel is loaded and starts its execution, it can start provide services to users.

Computer System Organization

- ▶ Computer-system operation
 - ▶ One or more CPUs, device controllers connect through common bus providing access to shared memory
 - ▶ Concurrent execution of CPUs and devices competing for memory cycles

- ▶ The CPU can load instructions only from memory
- ▶ So any Program to run must be stored in the primary memory
- ▶ Computer runs program from main memory
- ▶ All form of memory provides an array of bytes.
- ▶ Each byte has its own address
- ▶ Instructions are either load or stored
- ▶ Execution Cycle:
 - ▶ First fetches an instruction from memory and stores in instruction register .
 - ▶ Instruction is decoded and executed
 - ▶ Result is written back to memory

Note: It is necessary to store every thing in main memory permanently but it is not possible as RAM is

1. Small
2. Volatile

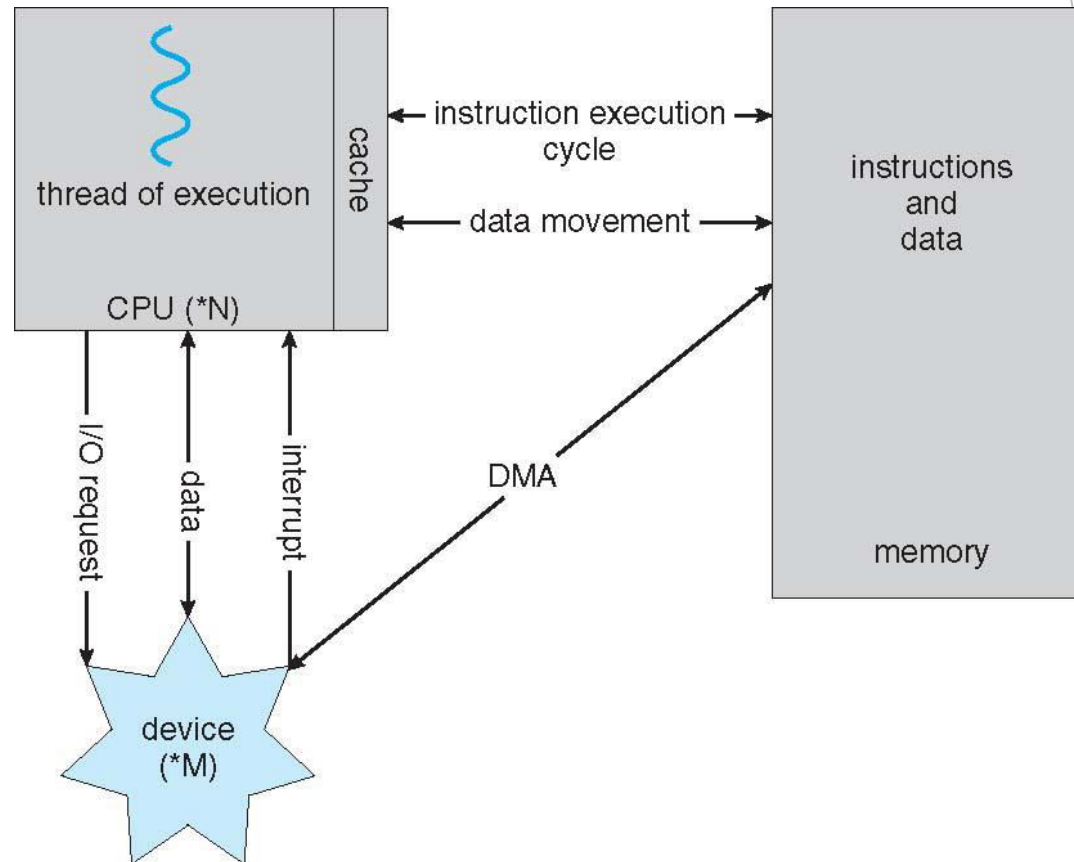

Storage-Device Hierarchy

I/O Structure

- ▶ I/O is one of major task of OS
- ▶ As it leads to reliability and performances of the system.
- ▶ CPU and multiple device controller are connected through common bus
- ▶ Each device controller is in charge of a specific device.
- ▶ An OS have a device driver for each device controller
- ▶ For bulk data transfer DMA is used.

How a Modern Computer Works

A von Neumann architecture

Storage Definitions and Notation Review

The basic unit of computer storage is the **bit**. A bit can contain one of two values, 0 and 1. All other storage in a computer is based on collections of bits. Given enough bits, it is amazing how many things a computer can represent: numbers, letters, images, movies, sounds, documents, and programs, to name a few. A **byte** is 8 bits, and on most computers it is the smallest convenient chunk of storage. For example, most computers don't have an instruction to move a bit but do have one to move a byte. A less common term is **word**, which is a given computer architecture's native unit of data. A word is made up of one or more bytes. For example, a computer that has 64-bit registers and 64-bit memory addressing typically has 64-bit (8-byte) words. A computer executes many operations in its native word size rather than a byte at a time.

Computer storage, along with most computer throughput, is generally measured and manipulated in bytes and collections of bytes.

A **kilobyte**, or **KB**, is $1,024$ bytes

a **megabyte**, or **MB**, is $1,024^2$ bytes

a **gigabyte**, or **GB**, is $1,024^3$ bytes

a **terabyte**, or **TB**, is $1,024^4$ bytes

a **petabyte**, or **PB**, is $1,024^5$ bytes

Computer manufacturers often round off these numbers and say that a megabyte is 1 million bytes and a gigabyte is 1 billion bytes. Networking measurements are an exception to this general rule; they are given in bits (because networks move data a bit at a time).

Computer-System Architecture

- ▶ Most systems use a single general-purpose processor
 - ▶ Most systems have special-purpose processors as well
- ▶ **Multiprocessors** systems growing in use and importance
 - ▶ Also known as **parallel systems**, **tightly-coupled systems**
 - ▶ Advantages include:
 1. **Increased throughput**
 2. **Economy of scale**
 3. **Increased reliability** - graceful degradation or fault tolerance
 - ▶ Two types:
 1. **Asymmetric Multiprocessing** - each processor is assigned a specific task.
 2. **Symmetric Multiprocessing** - each processor performs all tasks

Symmetric Multiprocessing Architecture

A Dual-Core Design

- ▶ **multicore(Multiple computing cores,single chip)**
- ▶ Systems containing in a single chips
 - ▶ Chassis containing multiple separate systems

Clustered Systems

- ▶ Like multiprocessor systems, but multiple systems working together
 - ▶ Usually sharing storage via a **storage-area network (SAN)**
 - ▶ Provides a **high-availability** service which survives failures
 - ▶ **Asymmetric clustering** has one machine in hot-standby mode
 - ▶ **Symmetric clustering** has multiple nodes running applications, monitoring each other
 - ▶ Some clusters are for **high-performance computing (HPC)**
 - ▶ Applications must be written to use **parallelization**

Clustered Systems

Memory Layout for Multiprogrammed System

- ▶ An OS provides an environment for programs to execute
- ▶ One important aspect of OS is multiprogramming

Operating System Structure

- ▶ One important aspect is ability to multi program
- ▶ **Multiprogramming (Batch system)** needed for efficiency
 - ▶ Single user cannot keep CPU and I/O devices busy at all times
 - ▶ Multiprogramming organizes jobs (code and data) so CPU always has one to execute
 - ▶ A subset of total jobs in system is kept in memory
 - ▶ One job selected and run via **job scheduling**
 - ▶ When it has to wait (for I/O for example), OS switches to another job
- ▶ **Timesharing (multitasking)** is logical extension in which CPU switches jobs so frequently that users can interact with each job while it is running, creating **interactive** computing
 - ▶ Each user has at least one program executing in memory ⇒ **process**
 - ▶ If several jobs ready to run at the same time ⇒ **CPU scheduling**

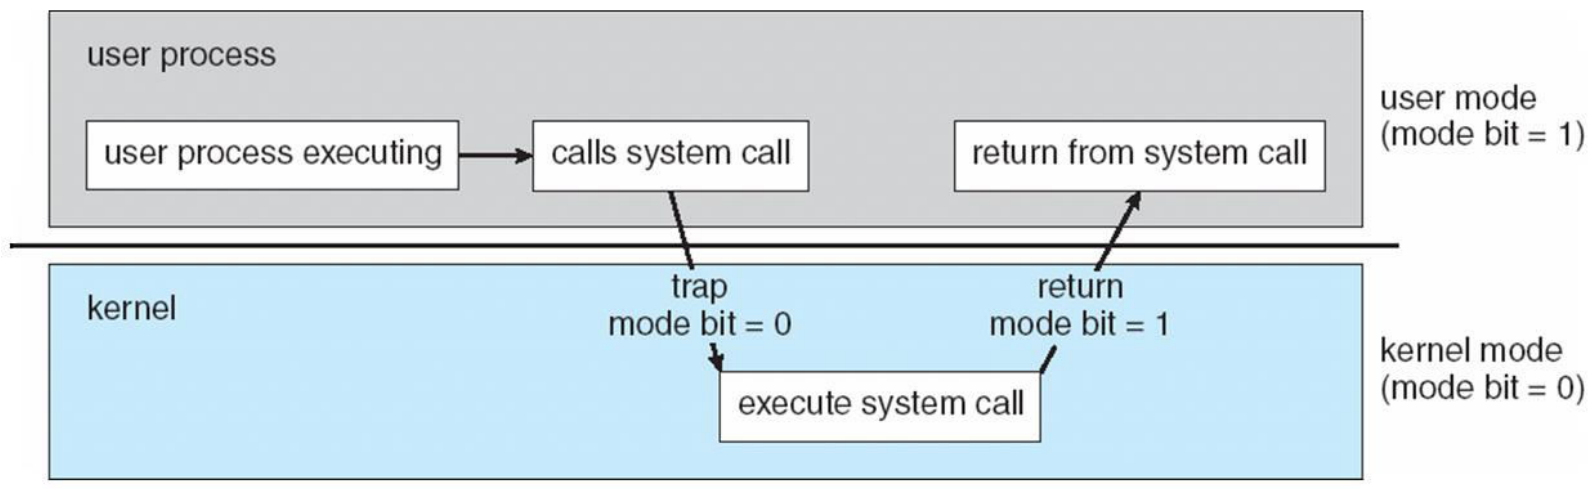

Operating-System Operations

- ▶ **Interrupt driven** (hardware and software)
 - ▶ Hardware interrupt by one of the devices
 - ▶ Software interrupt (**exception** or **trap**):
 - ▶ Software error (e.g., division by zero)
 - ▶ Request for operating system service
 - ▶ Other process problems include infinite loop, processes modifying each other or the operating system

Operating-System Operations (cont.)

- ▶ **Dual-mode** operation allows OS to protect itself and other system components
 - ▶ **User mode** and **kernel mode**
 - ▶ **Mode bit** provided by hardware
 - ▶ Provides ability to distinguish when system is running user code or kernel code
 - ▶ Some instructions designated as **privileged**, only executable in kernel mode
 - ▶ System call changes mode to kernel, return from call resets it to user
- ▶ Increasingly CPUs support multi-mode operations
 - ▶ i.e. **virtual machine manager (VMM)** mode for guest **VMs**

Transition from User to Kernel Mode

Process Management

- ▶ A process is a program in execution. It is a unit of work within the system. Program is a *passive entity*, process is an *active entity*.
- ▶ Process needs resources to accomplish its task
 - ▶ CPU, memory, I/O, files
 - ▶ Initialization data
- ▶ Process termination requires reclaim of any reusable resources
- ▶ Single-threaded process has one **program counter** specifying location of next instruction to execute
 - ▶ Process executes instructions sequentially, one at a time, until completion
- ▶ Multi-threaded process has one program counter per thread
- ▶ Typically system has many processes, some user, some operating system running concurrently on one or more CPUs
 - ▶ Concurrency by multiplexing the CPUs among the processes / threads

Memory Management

- ▶ To execute a program all (or part) of the instructions must be in memory
- ▶ All (or part) of the data that is needed by the program must be in memory.
- ▶ Memory management determines what is in memory and when
 - ▶ Optimizing CPU utilization and computer response to users
- ▶ Memory management activities
 - ▶ Keeping track of which parts of memory are currently being used and by whom
 - ▶ Deciding which processes (or parts thereof) and data to move into and out of memory
 - ▶ Allocating and deallocating memory space as needed

Storage Management

- ▶ OS provides uniform, logical view of information storage
 - ▶ Abstracts physical properties to logical storage unit - **file**
 - ▶ Each medium is controlled by device (i.e., disk drive, tape drive)
 - ▶ Varying properties include access speed, capacity, data-transfer rate, access method (sequential or random)
- ▶ File-System management
 - ▶ Files usually organized into directories
 - ▶ Access control on most systems to determine who can access what
 - ▶ OS activities include
 - ▶ Creating and deleting files and directories
 - ▶ Primitives to manipulate files and directories
 - ▶ Mapping files onto secondary storage
 - ▶ Backup files onto stable (non-volatile) storage media

Performance of Various Levels of Storage

Level	1	2	3	4	5
Name	registers	cache	main memory	solid state disk	magnetic disk
Typical size	< 1 KB	< 16MB	< 64GB	< 1 TB	< 10 TB
Implementation technology	custom memory with multiple ports CMOS	on-chip or off-chip CMOS SRAM	CMOS SRAM	flash memory	magnetic disk
Access time (ns)	0.25 - 0.5	0.5 - 25	80 - 250	25,000 - 50,000	5,000,000
Bandwidth (MB/sec)	20,000 - 100,000	5,000 - 10,000	1,000 - 5,000	500	20 - 150
Managed by	compiler	hardware	operating system	operating system	operating system
Backed by	cache	main memory	disk	disk	disk or tape

Movement between levels of storage hierarchy can be explicit or implicit

Migration of data “A” from Disk to Register

- ▶ Multitasking environments must be careful to use most recent value, no matter where it is stored in the storage hierarchy

- ▶ Multiprocessor environment must provide **cache coherency** in hardware such that all CPUs have the most recent value in their cache
- ▶ Distributed environment situation even more complex

I/O Subsystem

- ▶ One purpose of OS is to hide peculiarities of hardware devices from the user
- ▶ I/O subsystem responsible for
 - ▶ Memory management of I/O including buffering (storing data temporarily while it is being transferred), caching (storing parts of data in faster storage for performance), spooling (the overlapping of output of one job with input of other jobs)
 - ▶ General device-driver interface
 - ▶ Drivers for specific hardware devices

Protection and Security

- ▶ **Protection** - any mechanism for controlling access of processes or users to resources defined by the OS
- ▶ **Security** - defense of the system against internal and external attacks
 - ▶ Huge range, including denial-of-service, worms, viruses, identity theft, theft of service
- ▶ Systems generally first distinguish among users, to determine who can do what
 - ▶ User identities (**user IDs**, security IDs) include name and associated number, one per user
 - ▶ User ID then associated with all files, processes of that user to determine access control
 - ▶ Group identifier (**group ID**) allows set of users to be defined and controls managed, then also associated with each process, file
 - ▶ **Privilege escalation** allows user to change to effective ID with more rights

Kernel Data Structures

- Many similar to standard programming data structures
- ***Singly linked list***

Kernel Data Structures

- ▶ **Binary search tree**

left \leq right

- ▶ Search performance is $O(n)$

- ▶ **Balanced binary search tree** is $O(\lg n)$

Computing Environments - Client-Server

- Client-Server Computing
 - Dumb terminals supplanted by smart PCs
 - Many systems now **servers**, responding to requests generated by **clients**
 - ▶ **Compute-server system** provides an interface to client to request services (i.e., database)
 - ▶ **File-server system** provides interface for clients to store and retrieve files

Computing Environments - Peer-to-Peer

- ▶ Another model of distributed system
- ▶ P2P does not distinguish clients and servers
 - ▶ Instead all nodes are considered peers
 - ▶ May each act as client, server or both
 - ▶ Node must join P2P network
 - ▶ Registers its service with central lookup service on network, or
 - ▶ Broadcast request for service and respond to requests for service via *discovery protocol*
- ▶ Examples include Napster and Gnutella, **Voice over IP (VoIP)** such as Skype

Computing Environments - Virtualization

- ▶ Allows operating systems to run applications within other OSes
 - ▶ Vast and growing industry
- ▶ **Emulation** used when source CPU type different from target type (i.e. PowerPC to Intel x86)
 - ▶ Generally slowest method
 - ▶ When computer language not compiled to native code - **Interpretation**
- ▶ **Virtualization** - OS natively compiled for CPU, running **guest** OSes also natively compiled
 - ▶ Consider VMware running WinXP guests, each running applications, all on native WinXP **host** OS
 - ▶ **VMM** (virtual machine Manager) provides virtualization services

Computing Environments - Cloud Computing

- ▶ Delivers computing, storage, even apps as a service across a network
- ▶ Logical extension of virtualization because it uses virtualization as the base for its functionality.
 - ▶ Amazon **EC2** has thousands of servers, millions of virtual machines, petabytes of storage available across the Internet, pay based on usage
- ▶ Many types
 - ▶ **Public cloud** - available via Internet to anyone willing to pay
 - ▶ **Private cloud** - run by a company for the company's own use
 - ▶ **Hybrid cloud** - includes both public and private cloud components
 - ▶ Software as a Service (**SaaS**) - one or more applications available via the Internet (i.e., word processor)
 - ▶ Platform as a Service (**PaaS**) - software stack ready for application use via the Internet (i.e., a database server)
 - ▶ Infrastructure as a Service (**IaaS**) - servers or storage available over Internet (i.e., storage available for backup use)

Computing Environments - Cloud Computing

- ▶ Cloud computing environments composed of traditional OSEs, plus VMMs, plus cloud management tools
 - ▶ Internet connectivity requires security like firewalls
 - ▶ Load balancers spread traffic across multiple applications

Computing Environments - Real-Time Embedded Systems

- ▶ Real-time embedded systems most prevalent form of computers
 - ▶ Vary considerable, special purpose, limited purpose OS, **real-time OS**
 - ▶ Use expanding
- ▶ Many other special computing environments as well
 - ▶ Some have OSes, some perform tasks without an OS
- ▶ Real-time OS has well-defined fixed time constraints
 - ▶ Processing ***must*** be done within constraint
 - ▶ Correct operation only if constraints met

Open-Source Operating Systems

- ▶ Operating systems made available in source-code format rather than just binary **closed-source**
- ▶ Counter to the **copy protection** and **Digital Rights Management (DRM)** movement
- ▶ Started by **Free Software Foundation (FSF)**, which has “copyleft” **GNU Public License (GPL)**
- ▶ Examples include **GNU/Linux** and **BSD UNIX** (including core of **Mac OS X**), and many more
- ▶ Can use VMM like VMware Player (Free on Windows), Virtualbox (open source and free on many platforms - <http://www.virtualbox.com>)
 - ▶ Use to run guest operating systems for exploration
